Abstract  
Image segmentation is an essential step in image processing, that aim to make image analyzing easier. Image segmentation can be done by grouping or partitioning the image pixels into identical sets (regions) by relying on some qualities such as color, or texture, etc. It's have been used in many field such as object detection, recognition tasks, medical imaging and much more. there are basically two primary approaches for image segmentation which are traditional approaches and soft computing approaches (SCA), a lot of methods have been proposed based on these two approaches. SCA have many advantage over traditional approaches like flexibility, cost-effective, high performance. SCA involve using fuzzy logic, Artificial Neural Network (ANN) and Genetic Algorithm. This paper focus on providing a state-of-the-art new review and summaries of researchers' work on image segmentation based on different SCA. That will help the new researchers to learn about these methods and then choosing a certain method from these for improving or developing it to produce a new method for image segmentation.  

Keywords: - Image Segmentation, Soft computing, Fuzzy logic, Neural network, Genetic algorithm  

I. Introduction  
An Image can store a lot of useful information. A digital image composed of a finite number of elements (these elements also known as pixels or picture/image elements), each element has a particular value and location. pixels are the smallest single element in the image, retaining a finite, discrete, quantized values that represent the brightness, intensity or gray level at any specific point [1]. Understanding the image and extracting data from it to do specific tasks is a key area of application for digital image technology, and image segmentation is the first stage in this process.  
Image segmentation considered as one of the fundamental steps in image processing [2], it attempts to automatically analyze or interpret an image. Segmentation fill the gap between low-level and high-level image processing [3], as shown in Figure 1. So image segmentation can be defined as the
process of dividing an image into several segments based on particular characteristics including color, texture, and intensity values etc, and that’s done in order to transform the image's representation into something more meaningful and easier to understand (similar in term of properties, attributes and features). It genuinely locates an image's objects and bounds. The degree to which this division is carried out is determined by the problem being solved; segmentation should finish once the application's objects of interest have been isolated. So Segmentation is a technique for converting a complicated image into a simpler image [4] [5]. There are many applications of Image segmentation, such as medical imaging (medical diagnosis, locate tumors and other pathologies, etc.), content based image retrieval, Recognition tasks(recognition of Face, fingerprint, Iris), Machine vision, industrial inspection, object detection (like detecting roads and bridges in satellite images, Face detection, etc.), and more [5].

Image segmentation can be accomplished using a variety of approaches. Traditional approaches and soft computing approaches. Traditional approaches are straightforward and easy to implement methods. They achieve and produce precise answers to the segmentation problem. Traditional approaches are usually classified into four categories based on how they work: (1) region-based segmentation, (2) clustering, (3) edge-based segmentation, and (4) thresholding. These approaches are inefficient because they cannot handle real-world complicated situations that tolerate partial truth, imprecision, uncertainty, and approximations; they are also time-consuming, inefficient, and labor-intensive.

As a result, Soft Computing approaches(SCA) are utilized to address such issues. Soft Computing's objective is to create artificial intelligence by replicating a human brain's reasoning capabilities to solve ambiguity or real-world complicated situations. Soft computing(SC) combines computing techniques with biological structures to create new methods for more dynamic, competent, and dependable solutions. SC is a collection of techniques that includes fuzzy logic (FL), artificial neural networks (ANN), and genetic algorithms (GA). SC approaches, unlike traditional approaches, are forgiving of imprecision, uncertainty, partial truth, and approximations. Working with their ownership function gives them greater freedom, which makes them more powerful. SCA are widely employed and valued by researchers because of their adaptability and accuracy. SCA have the added benefit of being cost-effective, high-performing, and dependable solutions to
difficult issues. SC techniques have been used in a variety of fields, including scientific study, medicine, engineering, and management. So, the contribution of this paper is to provides review and summaries of researchers' work on image segmentation based on different soft computing approaches (SCA). The goal is to bring together various aspects such as new techniques, emerging topics for segmentation depending on SCA, evaluation parameters, problems associated with it, future plans, and other resources so that researchers can focus on developing new methods for various image segmentation applications [6].

This paper is organized as follows, Section II, is focused on Review some of the new works in image segmentation based on different soft computing approaches. Section III presents the conclusion for soft computing approaches to image segmentation. Finally, the references are given in Section IV.

II. Soft Computing Approaches

For comparison, three different soft computing approaches to image segmentation are most commonly used. These are (1) Fuzzy based approaches, (2) Genetic Algorithm based approaches, and (3) Neural Network based approaches. The following are the specifics of Approaches:

1. Fuzzy based Approach

It is based on the degree of truth or falsehood principle. It's a probabilistic segmentation method based on a fuzzy logic framework. The input image is first fuzzified, then passed on for membership modification based on expert knowledge and a set of fuzzy logics and set theory. The final result is
achieved after passing the modified image through image defuzzification, Figure 2, show the general structure of fuzzy system. Fuzzy thresholding, fuzzy integral-based decision making, and fuzzy c-means clustering are examples of fuzzy-based approaches [7]. The summary of fuzzy logic (FL) newest articles are shown in Table 1.

The results show that the proposed PIT2FCM 1 significantly improves execution time over the PIT2FCM 2. PIT2FCM 1 appears to be best in accuracy and execution time results. |
2. Genetic Algorithm based Approaches

A genetic algorithm is a method for computing, it is an algorithm for searching optimal solutions. by modeling the biological evolution process through natural selection and genetic mechanisms. It creates individual populations, determines individual fitness, and selects regenerative individuals, crosses, and mutates to create new individuals based on fitness. It features a high level of robustness, parallelism, adaptability, and speed of convergence. It can be used to determine the segmentation threshold in image segmentation technology [14]. Image segmentation using genetic algorithm shown in Figure 2. The summary of genetic algorithm (GA) newest articles are shown in Table 2.

3. Neural Network based Approaches

The nervous system of a human processed information in the same way as a "Artificial neural network (ANN)" did during image processing operations. The weights between the layers of the network, also known as interconnectivity, are changed so that the network can learn or understand the knowledge. When the network has fully grasped or been trained on the knowledge, it is capable of determining the best solution output for the set of input data. Generalization is the most significant property of neural networks [21]. The architecture of artificial neural network illustrated in Figure 2. The summary of neural network (NN) newest articles are shown in Table 3.

III. Conclusion

In image processing, Segmentation is an important pre-processing step in the areas of image analysis. It is a critical and essential component of image recognition system and usually determines the quality of the final result. Different approaches have been introducing, but the accuracy is the main problem for all of these. Therefore, the use of soft computing approaches (SCA) was adopted. SCA involves, fuzzy based approach, genetic algorithm based approach, and neural network based approach. The contribution of this article's is to providing new reviews and summaries for some of the researchers' work on image segmentation based on soft computing approaches (SCA). These approaches were tested on a real-life images. The hopes that it will encourage academics to work on inventing new segmentation methods with more accurate results.

مستخلص البحث:

تعتبر تجزئة الصور خطوة أساسية في معالجة الصور، والتي تهدف إلى تبسيط تحليل الصور. يمكن إجراء تجزئة الصورة عن طريق تجميع أو تقسيم بكسلات الصورة إلى مجموعات (منطق) متعددة من خلال الاعتماد على بعض الصفات مثل اللون، أو الميلس، وما إلى ذلك. وقد تم استخدامها في العديد من المجالات مثل اكتشاف الأشياء، وفهم التعرف، والتصوير الطبي وفي الكثير من المجالات الأخرى. هناك طريقتان أساسيتان لتجزئة الصور وهما الطرق التقليدية وطرق الحوسبة اللينة (SCA) ، وقد تم اقتراح الكثير من الطرق بناءً على هذه النهجين. تتمتع طرق SCA بالمزايا التي تفوق الطرق التقليدية مثل المرنة والفعالية من حيث التكلفة والأداء العالي. تتضمن طرق SCA الخوارزمية الجينية. تركز (ANN) استخدام الملفات الضبابية والشبكة العصبية الاصطناعية هذه الورقة البحثية على تقديم مراجعة جديدة وحديثة وملخصات لعمل الباحثين على تجزئة الصور المختلفة. سيساعد ذلك الباحثين في التعرف على هذه الأساليب ثم اختيار بناءً على طرق SCA بعضها مميتة منها لتحسينها أو تطويرها لإنتاج طريقة جديدة لتجزئة الصور.

الكلمات المفتاحية:
تجزئة الصورة، الحوسبة اللينة، المنطق الضبابي، الشبكة العصبية، الخوارزمية الجينية.
